

Water is one of the Earth's most precious natural resources. It is widely used in Mechanical Systems for comfort cooling, heating and processing. Through innovative design technology, water can be used in these applications with significant waste reduction.

Through Water Reclamation Designs and Rain Water Harvesting, water can "live" multiple lives before entering the sewage drain and/or being reintroduced into the ground. Environmentally conscious designs can limit the chemicals used for the cooling process and allow less water to be introduced to these applications, which in turn can greatly reduce waste.
